## University of Colorado Department of Computer Science

## Chaotic Dynamics – CSCI 4446/5446 Spring 2017

Problem Set 7

Issued: 28 February 2017

Due: 7 March 2017

**Reading:** Strogatz, sections 6.0-6.5; Liz's notes on the variational equation; Parker&Chua, Appendix B.

## Bibliography:

## Problems:

1. [math] Derive the Jacobian  $D_{\vec{x}}\vec{F}$  for the Lorenz system:

$$\vec{F}(\vec{x}, a, r, b) = \begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} a(y - x) \\ rx - y - xz \\ xy - bz \end{bmatrix}$$
 (1)

2. [math] Write down the associated variational system  $\dot{\delta} = D_{\vec{x}}\vec{F}\delta$ . The product of the Jacobian matrix  $D_{\vec{x}}\vec{F}$  and the  $n \times n$  matrix of variations

$$\delta = \left[ \begin{array}{ccc} \delta_{xx} & \delta_{yx} & \delta_{zx} \\ \delta_{xy} & \delta_{yy} & \delta_{zy} \\ \delta_{xz} & \delta_{yz} & \delta_{zz} \end{array} \right]$$

yields an  $n \times n$  matrix of the derivatives of the variations  $\dot{\delta}$ .  $\delta_{xy}$ , for instance, is the component of the x-variation that comes from the previous y-variation, and  $\dot{\delta}_{xy}$  is its rate of change with time.

3. [programming] A combination of this variational derivative and the original system derivative from PS5 can be used to integrate the  $(n^2+n)$ -dimensional variational equation

$$\left\{ \begin{array}{c} \dot{\vec{x}} \\ \dot{\delta} \end{array} \right\} = \left\{ \begin{array}{c} \vec{F} \\ D_{\vec{x}} \vec{F} \cdot \delta \end{array} \right\}$$

from the initial condition

$$\left\{\begin{array}{c} \vec{x}_0 \\ I \end{array}\right\}$$

with  $t = t_0$ . The time evolution of the first n elements of this set of initial conditions follows the trajectory  $\phi_t(\vec{x}_0, t_0)$ . The row and column sums of the matrix formed by the next  $n^2$  elements are different ways to look at the evolved versions of the initial variations: the first column sum, for example, gives the x component of the evolved variation, while the first row sum tells you what the x-piece of the original variation has grown into.

Integrate the Lorenz variational equation using RK4 (not ARK4) from the following initial conditions for 100 steps. Use a=16, r=45, b=4, and a timestep of .001. In each case, give

- the components of the evolved matrix  $\delta$
- the evolved variations (the column sums of  $\delta$ )

at the endpoint of the trajectory. Use  $t_0 = 0$  (this is really immaterial, as the system is autonomous). You need only turn in these twelve numbers for each of the following questions; no plots or intermediate values are necessary.

- (a)  $[x \ y \ z \ \delta_{xx} \ \delta_{xy} \ \delta_{xz} \ \delta_{yx} \ \delta_{yy} \ \delta_{yz} \ \delta_{zx} \ \delta_{zy} \ \delta_{zz}] = [0 \ 1 \ 2 \ 1 \ 0 \ 0 \ 1 \ 0 \ 0 \ 1]$
- (b) [10 -5 2 1 0 0 0 1 0 0 0 1]
- (c) [0 -1 2 1 0 0 0 1 0 0 0 1]
- (d) Look carefully at the evolved matrices of variations and describe some of their interesting features. From which point [(a), (b), or (c)] do the variations grow fastest? In which direction (x, y, z)? Do you notice any symmetries or gross differences between the different points (e.g., "the y-variation grows really fast near point A, but less so near point B...")?
